## FLEXMOS™ Hex Low-side MOSFET Pre-driver

The NCV7518 / NCV7518A programmable six channel low-side MOSFET pre-driver is one of a family of FLEXMOS automotive grade products for driving logic-level MOSFETs. The product is controllable by a combination of serial SPI and parallel inputs. The device offers 3.3 V/ 5 V compatible inputs and the serial output driver can be powered from either 3.3 V or 5 V. An internal power-on reset provides controlled power up. A reset input allows external re-initialization and an enable input allows all outputs and diagnostics to be simultaneously disabled.

Each channel independently monitors its external MOSFET's drain voltage for fault conditions. Shorted load fault detection thresholds are fully programmable using an externally programmed reference voltage and a combination of discrete internal ratio values. The ratio values are SPI selectable and allow different detection thresholds for each channel.

Fault recovery operation for each channel is programmable and may be selected for latch-off or automatic retry. Status information for each channel is 3-bit encoded by fault type and is available through SPI communication.

The FLEXMOS family of products offers application scalability through choice of external MOSFETs.

### Features

- 16-bit SPI with Parity and Frame Error Detection
- 3.3 V/5 V Compatible Parallel and Serial Control Inputs
- 3.3 V/5 V Compatible Serial Output Driver
- Reset and Enable Inputs
- Open-drain Fault Flag
- Priority Encoded Diagnostics with Latched Unique Fault Type Data
  - ◆ Shorted Load, Short to GND
  - ◆ Open Load with Fast Charge Option
  - ◆ On and Off State Pulsed Mode Diagnostics
- Ratiometric Diagnostic References and Currents
- Programmable
  - ◆ Shorted Load Fault Detection Thresholds
  - ◆ Fault Recovery Mode
  - ◆ Blanking Timers
- Wettable Flanks Pb-Free Packaging
- NCV Prefix for Automotive and Other Applications Requiring Unique Site and Control Change Requirements; AEC-Q100 Qualified and PPAP Capable
- This is a Pb-Free Device

### Benefits

- Scalable to Load by Choice of External MOSFET

## PACKAGE PIN DESCRIPTION 32 PIN QFN EXPOSED PAD PACKAGE

Label	Description
FLTREF	Analog Fault Detect Threshold: 5 V Compliant
DRN0 – DRN5	Analog Drain Feedback
GAT0 – GAT5	Analog Gate Drive: 5 V Compliant
RSTB	Digital Master Reset Input: 3.3 V/5 V (TTL) Compatible
ENB	Digital Master Enable Input: 3.3 V/5 V (TTL) Compatible
IN0 – IN5	Digital Parallel Input: 3.3 V/5 V (TTL) Compatible
CSB	Digital Chip Select Input: 3.3 V/5 V (TTL) Compatible
SCLK	Digital Shift Clock Input: 3.3 V/5 V (TTL) Compatible
SI	Digital Serial Data Input: 3.3 V/5 V (TTL) Compatible
SO	Digital Serial Data Output: 3.3 V/5 V Compliant
FLTB	Digital Open-Drain Output: 3.3 V/5 V Compliant
VLOAD	Power Supply – Diagnostic References and Currents
VCC1	Power Supply – Low Power Path
GND	Power Return – Low Power Path – Device Substrate
VCC2	Power Supply – Gate Drivers
VDD	Power Supply – Serial Output Driver
VSS	Power Return – VLOAD, VCC2, VDD
EP	Exposed Pad – Connected to GND – Device Substrate

## MAXIMUM RATINGS (Voltages are with respect to device substrate.)

Rating	Value	Unit
DC Supply – $V_{LOAD}$	-0.3 to 40	V
DC Supply – $V_{CC1}$ , $V_{CC2}$ , $V_{DD}$	-0.3 to 5.8	V
Difference Between $V_{CC1}$ and $V_{CC2}$	±0.3	V
Difference Between GND (Substrate) and $V_{SS}$	±0.3	V
Drain Input Clamp Forward Voltage Transient ( $\leq 2$ ms, $\leq 1\%$ duty)	78	V
Drain Input Clamp Forward Current Transient ( $\leq 2$ ms, $\leq 1\%$ duty)	10	mA
Drain Input Clamp Energy Repetitive ( $\leq 2$ ms, $\leq 1\%$ duty)	1.56	mJ
Drain Input Clamp Reverse Current $V_{DRNX} \geq -1.0$ V	-50	mA
Input Voltage (Any Input Other Than Drain)	-0.3 to 5.8	V
Output Voltage (Any Output)	-0.3 to 5.8	V
Junction Temperature, $T_J$	-40 to 150	°C
Storage Temperature, $T_{STG}$	-65 to 150	°C
Peak Reflow Soldering Temperature: Lead-free 60 to 150 seconds at 217°C (Note 1)	260 peak	°C

Stresses exceeding those listed in the Maximum Ratings table may damage the device. If any of these limits are exceeded, device functionality should not be assumed, damage may occur and reliability may be affected.

- See or download ON Semiconductor's Soldering and Mounting Techniques Reference Manual, SOLDERRM/D.

## ATTRIBUTES

Characteristic		Value
ESD Capability Human Body Model per AEC-Q100-002	Drain Feedback Pins (Note 3) $V_{LOAD}$ Pin All Other Pins	$\geq \pm 4.0$ kV $\geq \pm 1.5$ kV $\geq \pm 2.0$ kV
Moisture Sensitivity	(Note 2)	MSL3
Package Thermal Resistance – Still-air Junction-to-Ambient, $R_{\theta JA}$ Junction-to-Exposed Pad, $R_{\Psi JPAD}$	(Note 4) (Note 5)	95°C/W 46°C/W 3.2°C/W

- See or download ON Semiconductor's Soldering and Mounting Techniques Reference Manual, SOLDERRM/D.
- With GND &  $V_{SS}$  pins tied together – path between drain feedback pins and GND, or between drain feedback pins.
- Based on JESD51-3, 1.2 mm thick FR4, 2S0P PCB, 2 oz. signal, 20 thermal vias to 400 mm<sup>2</sup> spreader on bottom layer.
- Based on JESD51-7, 1.2 mm thick FR4, 1S2P PCB, 2 oz. signal, 20 thermal vias to 80 x 80 mm 1 oz. internal spreader planes.

## RECOMMENDED OPERATING CONDITIONS

Symbol	Parameter	MIN	MAX	Unit
$V_{LOAD}$	Diagnostic References and Currents Power Supply Voltage	7.5	18.0	V
$V_{DRNX}$	Drain Input Feedback Voltage	-0.3	60	V
$V_{CC1}$	Main Power Supply Voltage	4.75	5.25	V
$V_{CC2}$	Gate Drivers Power Supply Voltage	$V_{CC1} - 0.3$	$V_{CC1} + 0.3$	V
$V_{DD}$	Serial Output Driver Power Supply Voltage	3.0	$V_{CC1}$	V
$V_{FLTREF}$	Fault Detect Threshold Reference Voltage	0.35	2.75	V
$V_{IN}$ High	Logic High Input Voltage	2.0	$V_{CC1}$	V
$V_{IN}$ Low	Logic Low Input Voltage	0	0.8	V
$T_A$	Ambient Still-air Operating Temperature	-40	125	°C
$t_{RESET}$	Startup Delay at Power-on Reset (POR) (Note 6)	500	-	µs

- Minimum wait time until device is ready to accept serial input data.

### DETAILED OPERATING DESCRIPTION

#### General

The NCV7518 is a six channel general-purpose low-side pre-driver for controlling and protecting N-type logic level MOSFETs. Programmable fault detection and protection modes allow the device to accommodate a wide range of external MOSFETs and loads, providing flexible application solutions. Separate power supply pins are provided for low and high current paths to improve analog accuracy and digital signal integrity.

#### Power Up/Down Control

An internal Power-On Reset (POR) monitors  $V_{CC1}$  and causes all  $GAT_X$  outputs to be held low until sufficient voltage is available to allow proper control of the device. All internal registers are initialized to their defaults, status data is cleared, and the open-drain fault flag (FLT<sub>B</sub>) is disabled.

When  $V_{CC1}$  exceeds the POR threshold, the device is initialized and ready to accept input data. When  $V_{CC1}$  falls below the POR threshold during power down, FLT<sub>B</sub> is disabled and all  $GAT_X$  outputs are driven and held low until  $V_{CC1}$  falls below about 1.5 V.

#### RSTB and ENB Inputs

The active-low RSTB input with a resistive pull-down allows device reset by an external signal. When RSTB is brought low, all  $GAT_X$  outputs, the timer clock, the SPI, and the FLT<sub>B</sub> flag are disabled. All internal registers are initialized to their default states, status data is cleared, and the SPI and FLT<sub>B</sub> are enabled when RSTB goes high.

The active-low ENB input with resistive pull-up provides a global enable. ENB disables all  $GAT_X$  outputs and diagnostics, and resets the auto-retry timer when brought high. The SPI is enabled, fault data is not cleared and registers remain as programmed. Faulted outputs are re-enabled when ENB goes low.

#### SPI Communication

The NCV7518 is a 16-bit slave device. Communication between the host and the device may either be parallel via individual CSB addressing or daisy-chained through other devices using a compatible SPI protocol.

The active-low CSB chip select input has a pull-up resistor. The SI and SCLK inputs have pull-down resistors. The recommended idle state for SCLK is low. The tri-state SO line driver is powered via the  $V_{DD}$  and the  $V_{SS}$  pins, and can be supplied with either 3.3 V or 5 V.

The device employs odd parity, and frame error detection that requires integer multiples of 16 SCLK cycles during each CSB high-low-high cycle (valid communication frame.) A parity or frame error does not affect the FLT<sub>B</sub> flag.

The host initiates communication when a selected device's CSB pin goes low. Output data is simultaneously sent MSB first from the SO pin while input data is received MSB first at the SI pin under synchronous control of the master's SCLK signal while CSB is held low (Figure 10). Output data changes on the falling edge of SCLK and is guaranteed valid before the next rising edge of SCLK. Input data received must be valid before the rising edge of SCLK.

## NCV7518, NCV7518A

When CSB goes low, frame error detection is initialized, output data is transferred to the SPI, and the FLTB flag is disabled and reset if previously set.

If a valid frame has been received when CSB goes high, the last multiple of 16 bits received is decoded into command data, and FLTB is re-enabled. The FLTB flag will be set if a fault is detected.

If a frame or parity error is detected when CSB goes high, new command data is ignored, and previous fault data

remains latched and available for retrieval during the next valid frame. The FLTB flag will be set if a fault (not a frame or parity error) is detected.

The interaction between CSB and FLTB facilitates fault polling. When multiple NCV7518 devices are configured for parallel SPI access with individual CSB addressing, the device reporting a fault can be identified by pulsing each CSB in turn.

**Figure 10. SPI Communication Frame Format**

### Serial Data and Register Structure

The 16-bit data received by the NCV7518 is decoded into a 3-bit address, a 12-bit data word, and an odd parity bit (Figure 11). The upper three bits, beginning with the received MSB, are fully decoded to address one of eight

registers. The valid register addresses are shown in Table 1. The input command structure is shown in Table 3. Each register is later described in detail.

The 16-bit data sent by the NCV7518 is an echo of the previously received 3-bit address with the remainder of the 12-bit data and parity bit formatted into one of four response types – an echo of the previously received input data, the

diagnostic status information, the device revision information, or a transmission error (Table 2). The first response frame sent after reset (via POR or RSTB) is the device revision information.

**Gate & Mode Select – Register R0**

Each  $GAT_X$  output is turned on/off serially by programming its respective  $G_X$  bit (Table 4). When parallel inputs  $IN_X = 0$ , setting  $R0.G_X = 1$  causes the selected  $GAT_X$  output to drive its external MOSFET's gate to  $V_{CC2}$  (ON). Setting  $R0.G_X = 0$  causes the selected  $GAT_X$  output to drive its external MOSFET's gate to  $V_{SS}$  (OFF.) Note that the actual state of the output depends on POR, RSTB, ENB and shorted load fault states ( $SHRT_X$ ) as later defined by Equation 1. Default after reset is  $R0.D[11:0] = 0$  (all channels latch-off mode, all outputs OFF.) R0 is an echo type response register.

The disable mode for shorted load (on-state) faults is controlled by each channel's respective  $M_X$  bit. Setting  $R0.M_X = 0$  causes the selected  $GAT_X$  output to latch-off when a fault is detected. Setting  $R0.M_X = 1$  causes the selected  $GAT_X$  output to auto-retry when a fault is detected.

Recovery from latch-off is performed for all channels by disabling then re-enabling the device via the ENB input. Recovery for selected channels is performed by reading the status registers (R4, R5) for the faulted channels then executing a diagnostic ON or OFF pulse for the desired channels.

## NCV7518, NCV7518A

When auto-retry is selected, input changes for turn-on time are ignored while the retry timer is active. Once active, the timer will run to completion of the programmed time.

The output will follow the input at the end of the retry interval. The timer is reset when ENB = 1 or when the mode is changed to latch-off.

				1 = AUTO RETRY DEFAULT = LATCH OFF						1 = GATx ON DEFAULT = ALL OFF						

### Diagnostic Pulse Select – Register R1

The NCV7518 has functionality to perform either on-state or off-state diagnostic pulses (Table 5) The function is provided for applications having loads normally in a continuous on or off state. The diagnostic pulse function is available for both latch-off and auto-retry modes. The pulse executes for the selected channel(s) on low-high transition on CSB. Default after reset is R1.D[11:0] = 0. R1 is an echo type response register.

Diagnostic pulses have priority and are not dependant on the input (IN<sub>X</sub>, G<sub>X</sub>) or the output (GAT<sub>X</sub>) states. The pulse does not execute if: ENB =1 (device is disabled); both an ON and OFF pulse is simultaneously requested for the same channel; an ON or OFF pulse is requested and a SCB (shorted load) diagnostic code is present for the selected channels; an ON or OFF pulse is requested while a pulse is currently executing in the selected channels (i.e. a blanking

timer is active); the selected channels are currently under auto-retry control (i.e. refresh timer is active).

When R1.F<sub>X</sub> = 1, the diagnostic OFF pulse command is executed. The open load diagnostic is turned on if disabled (see Diagnostic Config 2 – R3), the output changes state for the programmed t<sub>BL(OFF)</sub> blanking period, and the diagnostic status is latched if of higher priority than the previous status. ICHG current is turned on if enabled via R3. The output assumes the currently commanded state at the end of the pulse.

When R1.N<sub>X</sub> = 1, the diagnostic ON pulse command is executed. The output changes state for the programmed t<sub>BL(ON)</sub> blanking period, and the diagnostic status is latched if of higher priority than the previous status. The output assumes the currently commanded state at the end of the pulse. A flowchart for the diagnostic pulse is given in Figure 16.

### Diagnostic Config 1 – Register R2

The diagnostic Config 1 register programs the turn-on/off blanking time and shorted load fault detection references for each channel (Table 6) Bits R2.C[2:0] select which channels receive the configuration data (Table 7). Bits R2.C[8:5] select turn-on/off blanking time (Table 8). Bits R2.C[11:9]

select the fault reference (Table 9). Default after reset is indicated by “(DEF)” in the tables. R2 is an echo type response register.

If a blanking timer is currently running when the register is changed, the new value is accepted but will not take effect until the next activation of the timer.

### Diagnostic Config 2 – Register R3

Off-state open load diagnostic currents for each channel can be enabled or disabled for LED loads. Short to GND diagnostic is unaffected. Fast charge current (ICHG) can be enabled or disabled for capacitive loads. Channels are selected by bit positions in the register (Table 10.) Open load

status (OLF) information is suppressed when the diagnostic is turned off via R3. Open load diagnostic and OLF status is temporarily enabled when a diagnostic off pulse is executed via R1. Default after reset is R3.D[11:6] = 0 and R3.D[5:0] = 1. R3 is an echo type response register.

**Diagnostic Status Registers – Register R4 & R5**

Diagnostic status and ENB status information is returned when R4 or R5 is selected (Table 11) Diagnostic status information for each channel is 3-bit (ST2:0) priority

encoded (Table 12). Bit D[9] returns the state of the ENB input e.g. D[9] = 0 when ENB = 0 (enabled). Default response after reset or SPI read is D[8:0] = 1 (“Diagnostic Not Complete”).

**Table 11. DIAGNOSTIC STATUS REGISTERS**

1	0	0	Diagnostic Complete – No Fault	4
1	0	1	No SCB Fault – ON State	5
1	1	0	No SCG/OLF Fault – OFF State	6
1	1	1	Diagnostic Not Complete (DEFAULT)	7 LOWEST

NOTE: OLF status report is suppressed when open load diagnostic is turned off via Diagnostic Config 2 – register R3

Status is latched for the currently higher priority fault and is not demoted if a fault of lower priority occurs. The status registers are reset to “Diagnostic Not Complete” after reading the registers, or by asserting a reset via RSTB. Status registers are not affected by ENB.

bits D[5:3] are hard coded with the die (silicon) revision, and bits D[2:0] are hard coded with the mask (interconnect) revision. The first response frame sent after reset is the device revision information. The revision encoding scheme is shown in Table 14.

**Revision Information – Register R6**

Device revision information is returned when R6 is selected (Table 13). Output bits D[11:6] are hard coded to 0,

Mask revision may be incremented when an interconnect revision is made. Die revision is incremented when a silicon revision is made. Mask revision is reset to “000” when a die revision is made.

**Table 13. DEVICE REVISION INFORMATION**

**Reserved – Register R7**

Register R7 is reserved for factory test use. Data sent to R7 is ignored. In normal operation, R7 is an echo type response

register. In the event of a transmission error, R7 responds with either a parity or frame error on the next valid frame.

Table 15. TEST MODE REGISTER

**Gate Driver Control and Enable**

Each GAT<sub>X</sub> output may be turned on by either its respective parallel IN<sub>X</sub> input or the Gate & Mode Select register bits R0.G[5:0] via SPI communication. The device’s RSTB reset and ENB enable inputs can be used to implement global control functions, such as system reset, over-voltage or input override by a watchdog controller.

The RSTB input has an internal pull-down resistor and the ENB input has an internal pull-up resistor. Each parallel input has an internal pull-down resistor. Parallel input is recommended when low frequency (≤ 10 kHz) PWM operation of the outputs is desired. Unused parallel inputs should be connected to GND.

When RSTB is brought low, all GAT<sub>X</sub> outputs, the timer clock, the SPI, and the FLTB flag are disabled. All internal registers are initialized to their default states, status data is cleared, and the SPI and FLTB are enabled when RSTB goes high.

ENB disables all GAT<sub>X</sub> outputs and diagnostics, and resets the auto-retry timer when brought high. The SPI is enabled, fault data is not cleared and registers remain as programmed. Faulted outputs are re-enabled when ENB goes low.

The IN<sub>X</sub> input state and the G<sub>X</sub> register bit data are logically combined with the internal (active low) power-on reset signal (POR), the RSTB and ENB input states, and the shorted load state (internal SHRT<sub>X</sub>) to control the corresponding GAT<sub>X</sub> output such that:

$$GAT_X = POR \cdot RSTB \cdot ENB \cdot SHRT_X \cdot (IN_X + G_X) \tag{eq. 1}$$

The GAT<sub>X</sub> state truth table is given in Table 16.

Table 16. GATE DRIVER TRUTH TABLE

POR	RSTB	ENB	SHRT <sub>x</sub>	IN <sub>x</sub>	G <sub>x</sub>	GAT <sub>x</sub>
0	X	X	X	X	X	L
1	0	X	X	X	X	L
1	1	1	X	X	X	L
1	1	0	1	0	0	L
1	1	0	1	1	X	H
1	1	0	1	X	1	H
1	1	0	0	X	X	→L
1	1	0→1	X	X	G <sub>x</sub>	→L
1	1	1→0	→1	0	G <sub>x</sub>	→G <sub>x</sub>
1	1→0	X	X	X	→0	→L

**Gate Drivers**

The non-inverting GAT<sub>x</sub> drivers are symmetrical resistive switches (350 Ω typ.) to the VCC2 and VSS voltages. While the outputs are designed to provide symmetrical gate drive to an external MOSFET, load current

switching symmetry is dependent on the characteristics of the external MOSFET and its load. Figure 12 shows the gate driver block diagram.

Figure 12. Gate Driver Channel

**Blanking and Filter Timers**

Blanking timers are used to allow drain feedback to stabilize after a channel is commanded to change states. Filter timers are used to suppress glitches while a channel is in a stable state.

A turn-on blanking timer is started when a channel is commanded on. Drain feedback is sampled after t<sub>BL(ON)</sub>. A turn-off blanking timer is started when a channel is commanded off. Drain feedback is sampled after t<sub>BL(OFF)</sub>.

A filter timer is started when a channel is in a stable state and a fault detection threshold associated with that state has been crossed. Drain feedback is sampled after t<sub>FF(ON|OFF)</sub>. A filter timer may also be started while a blanking timer is active, so the blanking interval could be extended by the filter time.

Each channel has independent blanking and filter timers. The parameters for the t<sub>FF(ON|OFF)</sub> filter timer are the same for all channels. The turn-on/off blanking time for each channel can be selected via the Diagnostic Config 1 register bits R2.C[8:5] (Tables 6 and 8).

If a blanking timer is currently running when the register is changed, the new value is accepted but will not take effect until the next activation of the timer.

Blanking timers for all channels are started when both RSTB goes high and ENB goes low, when RSTB goes high while ENB is low, when ENB goes low while RSTB is high, or by POR.

**Fault Diagnostics and Behavior**

Each channel has independent fault diagnostics and employs blanking and filter timers to suppress false faults. An external MOSFET is monitored for fault conditions by connecting its drain to a channel’s DRN<sub>x</sub> feedback input through an optional external series resistor.

Shorted load (or short to V<sub>LOAD</sub>) faults can be detected when a driver is on. Open load or short to GND faults can be detected when a driver is off.

On-state faults will initiate MOSFET protection behavior, set the FLT<sub>B</sub> flag and the respective channel’s status bits in

the device's status registers. Off-state faults will simply set the FLTB flag and the channel's status bits.

Status information is retrieved by SPI read of registers R4 and R5 (Table 11). Status information for each channel is 3-bit priority encoded (Table 12). Shorted load fault has priority over open load and short to GND. Short to GND has priority over open load. Priority ensures that the most severe fault data is available at the next SPI read.

Status is latched for the currently higher priority fault and is not demoted if a fault of lower priority occurs. The status registers are reset to "Diagnostic Not Complete" after reading the registers, or by asserting a reset via RSTB. Status registers are not affected by ENB.

When either RSTB is low or ENB is high, diagnostics are disabled. When RSTB is high and ENB is low, open load diagnostics are enabled according to the state of the Diagnostic Config 2 register bits R3.D[5:0] (Table 10).

### Diagnostic Pulse Mode

The NCV7518 has functionality to perform either on-state or off-state diagnostic pulses (Table 5). The function is provided for applications having loads normally in a continuous on or off state. The diagnostic pulse function is available for both latch-off and auto-retry modes. The pulse executes for the selected channel(s) on low-high transition on CSB.

Diagnostic pulses have priority and are not dependant on the input ( $IN_X$ ,  $G_X$ ) or the output ( $GAT_X$ ) states. The pulse does not execute if: ENB = 1 (device is disabled); both an ON and OFF pulse is simultaneously requested for the same channel; an ON or OFF pulse is requested and a SCB (shorted load) diagnostic code is present for the selected channels; an ON or OFF pulse is requested while a pulse is currently executing in the selected channels (i.e. a blanking timer is active); the selected channels are currently under auto-retry control (i.e. refresh timer is active).

When  $R1.F_X = 1$ , the diagnostic OFF pulse command is executed. The open load diagnostic is turned on if disabled (see Diagnostic Config 2 – R3), the output changes state for the programmed  $t_{BL(OFF)}$  blanking period, and the diagnostic status is latched if of higher priority than the previous status. ICHG current is turned on if enabled via R3. The output assumes the currently commanded state at the end of the pulse.

When  $R1.N_X = 1$ , the diagnostic ON pulse command is executed. The output changes state for the programmed  $t_{BL(ON)}$  blanking period, and the diagnostic status is latched if of higher priority than the previous status. The output assumes the currently commanded state at the end of the pulse. A flowchart for the diagnostic pulse is given in Figure 16.

### Shorted Load Detection

An external reference voltage applied to the FLTREF input serves as a common reference for all channels (Figures 1 and 2). The FLTREF voltage should be within the

range of 0.35 to 2.75 V and can be derived via a voltage divider between  $V_{CC1}$  and GND.

Shorted load detection thresholds can be programmed via SPI in eight increments that are ratiometric to the applied FLTREF voltage. Separate thresholds can be selected for each channel via the Diagnostic Config 1 register bits R2.C[11:9] (Tables 6 and 9).

A shorted load fault is detected when a channel's  $DRN_X$  feedback is greater than its selected fault reference after either the turn-on blanking or the filter has timed out.

### Shorted Load Fault Disable and Recovery

Shorted load fault disable mode for each channel is individually SPI programmable via the device's Gate & Mode select register bits R0.M[5:0] (Table 4).

When latch-off mode (default) is selected, the corresponding  $GAT_X$  output is latched off upon detection of a fault. Recovery from latch-off is performed for all channels by disabling then re-enabling the device via the ENB input. Recovery for selected channels is performed by reading the status registers (R4, R5) for the faulted channels then executing a diagnostic ON or OFF pulse for the desired channels.

When auto-retry mode is selected the corresponding  $GAT_X$  output is turned off upon detection of a fault for the duration of the fault retry time ( $t_{FR}$ ). When auto-retry is selected, input changes for turn-on blanking time are ignored while the retry timer is active. Once active, the timer will run to completion of the programmed time. The output will follow the input at the end of the retry interval. The timer is reset when ENB = 1 or when the mode is changed to latch-off.

The output is automatically turned back on (if still commanded on) when the retry time ends. The channel's  $DRN_X$  feedback is re-sampled after the turn-on blanking time. The output will automatically be turned off if a fault is again detected. This behavior will continue for as long as the channel is commanded on and the fault persists.

In either mode, a fault may exist at turn-on or may occur some time afterward. To be detected, the fault must exist longer than either  $t_{BL(ON)}$  at turn-on or longer than  $t_{FF(ON)}$  some time after turn-on. The length of time that a MOSFET stays on during a shorted load fault is thus limited to either  $t_{BL(ON)}$  or  $t_{FF(ON)}$ .

### Recovery Retry Time

A global retry timer is used for auto-retry timing. The first faulted channel triggers the timer and the full retry time is guaranteed for that channel. An additional faulted channel may initially retry immediately after its turn-on blanking time, but subsequent retries will have the full retry time.

If all channels become faulted, they will become synchronized to the global retry timer.

**Open Load and Short to GND Detection**

A window comparator with references and bias currents proportional to  $V_{LOAD}$  is used to detect open load or short to GND faults when a channel is off. Each channel's  $DRN_X$  feedback is compared to the references after either the turn-off blanking or the filter has timed out. Figure 13 shows the  $DRN_X$  bias and fault detection zones.

**Figure 13.  $DRN_X$  Bias and Fault Detection Zones**

No fault is detected if the feedback voltage at  $DRN_X$  is greater than the  $V_{OL}$  open load reference. If the feedback is

less than the  $V_{SG}$  short to GND reference, a short to GND fault is detected. If the feedback is less than  $V_{OL}$  and greater than  $V_{SG}$ , an open load fault is detected.

When either  $RSTB$  is low or  $ENB$  is high, diagnostics are disabled. When  $RSTB$  is high and  $ENB$  is low, off-state diagnostics are enabled according to the content of the Diagnostic Config 2 register bits  $R3.D[11:0]$  (Tables 10 and 17.)

0	X	OFF		(DEF)
1	X	ON		

Figure 14 shows the simplified detection circuitry. Bias currents  $I_{SG}$  and  $I_{OL}$  are applied to a bridge along with bias voltage  $V_{CTR}$ . Transient fast charge current  $I_{CHG}$  is supplied to help charge any capacitance present at the  $DRN_X$  node to suppress a false short to GND fault.

**Figure 14. Short to GND/Open-Load Detection**

The transient current is started when a channel's turn-off blanking time is started and terminated either when the  $DRN_X$  voltage reaches  $V_{CTR}$  or when the turn-off blanking time  $t_{BL(OFF)}$  expires.  $V_{DRNX}$  will remain at  $V_{CTR}$  if an open load truly exists, otherwise the capacitance can continue to charge via  $R_{LD}$ .

When a channel is off and  $V_{LD}$  and  $R_{LD}$  are present,  $R_{SG}$  is absent, and  $V_{DRNX} \gg V_{CTR}$ , bias current  $I_{OL}$  is supplied from  $V_{LD}$  to ground through resistors  $R_{LD}$  and optional  $R_{DX}$ , and bridge diode  $D2$ . Bias current  $I_{SG}$  is supplied from  $V_{LOAD}$  to  $V_{CTR}$  through  $D3$ . No fault is detected if the feedback voltage ( $V_{LD}$  minus the total voltage drop caused by  $I_{OL}$  and the resistance in the path) is greater than  $V_{OL}$ .

When  $R_{SG}$  and either  $V_{LD}$  or  $R_{LD}$  are absent, the bridge will self-bias so that  $V_{DRNX}$  will settle to about  $V_{CTR}$ . An open load fault can be detected since the feedback is between  $V_{SG}$  and  $V_{OL}$ .

Short to GND detection can tolerate up to a  $\pm 1.0$  V offset ( $V_{OS}$ ) between the NCV7518's GND and the short. When  $R_{SG}$  is present and  $V_{DRNX} \ll V_{CTR}$ , bias current  $I_{SG}$  is supplied from  $V_{LOAD}$  to  $V_{OS}$  through  $D1$ , and the  $R_{SG}$  and optional  $R_{DX}$  resistances. Bias current  $I_{OL}$  is supplied from  $V_{CTR}$  to ground through  $D4$ .

When  $V_{LD}$  and  $R_{LD}$  are present, a voltage divider between  $V_{LD}$  and  $V_{OS}$  is formed by  $R_{LD}$  and  $R_{SG}$ . A "soft" short to

GND may be detected in this case depending on the ratio of  $R_{LD}$  and  $R_{SG}$  and the values of  $R_{DX}$ ,  $V_{LD}$ , and  $V_{OS}$ .

Optional  $R_{DX}$  resistor is used when voltages greater than the 60 V minimum clamp voltage or down to -1 V are expected at the  $DRN_x$  inputs. Note that the comparators see a voltage drop or rise due to the  $R_{DX}$  resistance and the bias currents. This produces an error in the comparison of feedback voltage at the comparator inputs to the actual node voltage  $V_X$ .

Several equations for choosing  $R_{DX}$  and for predicting open load or short to GND resistances, and a discussion of the dynamic behavior of the short to GND/ open load diagnostic are provided in the “Application Guidelines” section of this data sheet.

### Fault Flag (FLT B)

The open-drain active-low fault flag output can be used to provide immediate fault notification to a host controller. Fault detection from all channels is logically ORed to the flag (Figure 15) The FLT B outputs from several devices can be wire-ORed to a common pull-up resistor connected to the controller’s 3.3 or 5 V  $V_{DD}$  supply.

When RSTB and CSB are high, and ENB is low, the flag is set (low) when any channel detects any fault. The flag is reset (hi-Z) and disabled during POR, when either RSTB or CSB is low, or when ENB is high. See Table 18 for details.

**Figure 15. FLT B Flag Logic**

The interaction between CSB and FLT B facilitates fault polling. When multiple NCV7518 devices are configured for parallel SPI access with individual CSB addressing, the device reporting a fault can be identified by pulsing each CSB in turn.

### Fault Detection and Capture

Each channel of the NCV7518 is capable of detecting shorted load faults when the channel is on, and short to ground or open load faults when the channel is off. Each fault type is priority encoded into 3-bit per channel fault data (Table 12.) Shorted load fault data has priority over open load and short to GND data. Short to GND data has priority over open load data. Priority ensures that the most severe fault data is available at the next SPI read.

A drain feedback input for each channel compares the voltage at the drain of the channel’s external MOSFET to several internal reference voltages. Separate detection references are used to distinguish the three fault types.

Blanking and filter timers are used respectively to allow for output state transition settling and for glitch suppression.

When enabled and configured, each channel’s drain feedback input is continuously compared to references appropriate to the channel’s input state to detect faults, but the comparison result is only latched at the end of either a blanking or filter timer event.

Blanking timers for all channels are started when both RSTB goes high and ENB goes low, when RSTB goes high while ENB is low, when ENB goes low while RSTB is high, or by POR. A single channel’s blanking timer is triggered when its input state changes. If the comparison of the feedback to a reference indicates an abnormal condition when the blanking time ends, a fault has been detected and the fault data is latched into the channel’s status register.

A channel’s filter timer is triggered when its drain feedback comparison state changes. If the change indicates an abnormal condition when the filter time ends, a fault has been detected and the fault data is latched into the channel’s status register.

Thus, a state change of the inputs (POR, RSTB, ENB,  $IN_X$  or  $G_X$ ) or a state change of an individual channel’s feedback ( $DRN_X$ ) comparison must occur for a timer to be triggered and a detected fault to be captured.

### Fault Capture, SPI Communication, and SPI Frame Error Detection

The NCV7518 latches a fault when it is detected, and parity and frame error detection will not allow any register to accept data if an invalid frame occurred.

The fault capture, parity, and frame error detection strategies combine to ensure that intermittent faults can be captured and identified, and that the device cannot be inadvertently re-programmed by a communication error.

When a fault has been detected, status information is latched into a channel’s status register if of higher priority than current status, and the FLT B flag is set. The register holds the status data and ignores subsequent lower priority status data for that channel.

Current status information is transferred from the selected status register into the SPI shift register at the start of the SPI frame following the read status request. This ensures that status updates continue during inter-frame latency between the status request and delivery. The FLT B flag is reset when CSB goes low.

The selected status register is cleared when CSB goes high at the end of the SPI frame only if a valid frame has occurred; otherwise the register retains status information until a valid read frame occurs. The FLT B flag will be set if a fault is still present.

Status registers and the FLT B flag can also be cleared by toggling RSTB H→L→H. A full I/O truth table is given in Table 18.

### Status Priority Encoding

Shorted load (SCB) faults can be detected when a driver is ON. Open load (OLF) or short to GND (SCG) faults can

be detected when a driver is OFF. Status memory is priority encoded in a 3-bit per driver format (Table 12).

Status memory will be encoded “Diagnostic Not Complete” during a blanking period unless a fault of higher priority has previously been encoded. Status memory will be encoded “Diagnostic Not Complete” (cleared) for the selected status register at the end of a valid SPI frame.

“Diagnostic Complete – No Fault” will be encoded when BOTH on-state AND off-state diagnostics have been completed unless a fault of higher priority has previously been encoded. A diagnostic cycle may start from either an off-state or an on-state.

When a diagnostic cycle starts from an off-state and no fault is detected, “No SCG/OLF Fault” will be encoded unless a fault of higher priority has previously been encoded. Otherwise, “OLF” or “SCG” will be encoded unless a fault of higher priority has previously been encoded. If the cycle continues to an on-state and no fault is detected, “Diagnostic Complete – No Fault” will be encoded. Otherwise, “SCB” will be encoded.

When a diagnostic cycle starts from an on-state and no fault is detected, “No SCB Fault” will be encoded unless a fault of higher priority has previously been encoded. Otherwise, “SCB” will be encoded. If the cycle continues to an off-state and no fault is detected, “Diagnostic Complete – No Fault” will be encoded unless a fault of higher priority has previously been encoded. Otherwise, “OLF” or “SCG” will be encoded unless a fault of higher priority has previously been encoded.

Status is latched for the currently higher priority fault and is not demoted if a fault of lower priority occurs. The status registers are reset to “Diagnostic Not Complete” after reading the registers, or by asserting a reset via RSTB. Status registers are not affected by ENB.

A Statechart diagram of the diagnostic status encoding is given in Figure 17 and additional clarification is given in “Appendix A – Diagnostic and Protection Behavior Tutorial”.

### VLOAD Undervoltage Detection

Undervoltage detection is used to suppress off-state diagnostics when VLOAD falls below the specified VLDUV operating voltage. This ensures that potentially incorrect diagnostic status is not captured. On-state diagnostics continue to operate normally and status information is updated appropriately for an off-to-on input transition during undervoltage.

Previous status information and FLTb are unchanged when entering or leaving undervoltage. Upon a read of the status registers during undervoltage, the status is changed to “Diagnostic Not Complete” and will remain as such for channels in an off-state during the entire undervoltage interval. Status information and FLTb are updated appropriately if a channel changes from off to on during the interval.

When VLOAD returns to its normal operating range, a channel’s  $t_{BL(OFF)}$  blanking timer is started if the channel was in an off state. Status information is updated appropriately after the  $t_{BL(OFF)}$  blanking interval, or after the  $t_{FF(OFF)}$  filter interval if the filter has been activated.

## APPLICATION GUIDELINES

### General

Unused  $DRN_X$  inputs should be connected to  $V_{LOAD}$  to prevent false open load faults. Unused parallel inputs should be connected to GND and unused reset or enable inputs should be connected to  $V_{CC1}$  or GND respectively. The user's software should be designed to ignore fault information for unused channels. For best shorted-load detection accuracy, the external MOSFET source terminals should be star-connected and the NCV7518's GND pin, and the lower resistor in the fault reference voltage divider should be Kelvin connected to the star (see Figure 2).

Consideration of auto-retry fault recovery behavior is necessary from a power dissipation viewpoint (for both the NCV7518 and the MOSFETs) and also from an EMI viewpoint.

Driver slew rate and turn-on/off symmetry can be adjusted externally to the NCV7518 in each channel's gate circuit by the use of series resistors for slew control, or resistors and diodes for symmetry. Any benefit of EMI reduction by this method comes at the expense of increased switching losses in the MOSFETs.

The channel fault blanking timers must be considered when choosing external components (MOSFETs, slew control resistors, etc.) to avoid false faults. Component choices must ensure that gate circuit charge/discharge times stay within the turn-on/turn-off blanking times.

The NCV7518 does not have integral drain-gate flyback clamps. Self-clamped MOSFET products, such as ON Semiconductor's NIF9N05CL or NCV8440A devices, are recommended when driving unclamped inductive loads. This flexibility allows choice of MOSFET clamp voltages suitable to each application.

### Latch-off Recovery and PWM Operation

When a channel is latched off and the recovery method chosen is the diagnostic pulse, the recovery attempt can be blocked by a PWM or other signal transition at the channel's parallel  $IN_x$  input. The transition starts an ON or OFF blanking timer which will prevent execution of a pulse request if the request via SPI is received while the timer is running.

This can be overcome by first sending  $G_x = 1$  via SPI (i.e. serial control) to override the channel's  $IN_x$  input, reading the diagnostic registers, then sending a pulse request. The channel can then be released back to parallel control by sending  $G_x = 0$ . Delays are added as necessary for the appropriate blanking times between each step. Global recovery may also be performed disabling then re-enabling the device via the ENB input.

### Auto-retry and OFF Pulse Interaction

A single hardware implementation serves as the global auto-retry ( $t_{FR}$ ) timer function for all channels and within each channel the turn-on ( $t_{BL(ON)}$ ) and turn-off ( $t_{BL(OFF)}$ ) blanking timers are shared (single hardware implementation) with  $t_{BL(ON)}$  time dominant. These same blanking timers also generate the ON or OFF diagnostic pulses.

If a channel configured for auto-retry is continuously commanded ON and becomes faulted (SCB), it remains ON and a turn-on blanking time is initiated every 8 ms for the faulted channel and also for each non-faulted ON channel configured for auto-retry. If a channel configured for auto-retry is commanded OFF, it remains OFF and no blanking timers are started.

When a diagnostic OFF pulse request is received just prior to an auto-retry cycle, the channel's  $t_{BL(OFF)}$  timer can be interrupted by the auto-retry timer ( $t_{BL(ON)}$  blanking time initiation). For example, a channel's  $t_{BL(OFF)}$  timer is programmed for 162  $\mu$ s and an OFF pulse is requested and begins execution, but before it can complete its timeout, the auto-retry initiates a  $t_{BL(ON)}$  blanking time. Due to the blanking timer sharing, the  $t_{BL(OFF)}$  timer does not complete its timeout and the pulse request becomes locked out.

The number of locked-out channels depends on which ones were programmed for auto-retry *and* which ones were requesting an OFF-pulse within the described zone of vulnerability. Further OFF pulse requests will fail to execute for each locked-out channel.

This interaction can be avoided for channels operated in a constant-on state by selecting the latch-off recovery mode and emulating the auto-retry mode. This can be done by sending a series of read status and diagnostic pulse execution requests with appropriate delays on a scheduled (e.g. every 10 ms) basis. Global recovery may also be performed disabling then re-enabling the device via the ENB input.

### Parity Error Handling

The SPI input (SI) shift register is reset (forced to 0x00) in case of an invalid frame resulting from either an incorrect frame length or incorrect parity. The 'live' parity check hardware implementation of the SI register content is blocked during a frame by CSB. When CSB goes high and the frame length is correct but parity is incorrect, parity check inputs may change as the SI register is forced to 0x00 and register data may be affected. In the event a parity error occurs it is recommended to refresh all of the device's configuration (write) registers. Register data is not affected if the frame length is incorrect.

## NCV7518, NCV7518A

### Appendix A – Diagnostic and Protection Behavior Tutorial

The following tutorial can be used together with Table 19 and the Statechart of Figure 17 to further understand how diagnostic status information is updated.

- ◆ Digital core is disabled if these conditions are not valid
- VCC2 present and in specified range
- VLOAD present and in specified range
  - ◆ VFLTREF present and in specified range
  - ◆  $IN_x \text{ OR } G_x = 1 \text{ AND ENB } 1 \rightarrow 0$
  - ◆  $ENB = 0 \text{ AND } IN_x \text{ OR } G_x 0 \rightarrow 1$
  - ◆  $ENB = 0 \text{ AND ON-State Diagnostic Pulse Request}$
  - ◆ Blanking and/or Filter timer ran till end
    - √ “Diagnostic Complete”
- ◆ VLOAD present and in specified range
- ◆  $IN_x \text{ AND } G_x = 0 \text{ AND ENB } 1 \rightarrow 0$
- ◆  $ENB = 0 \text{ AND } IN_x 1 \rightarrow 0 \text{ AND } G_x = 0$
- ◆  $ENB = 0 \text{ AND } IN_x = 0 \text{ AND } G_x 1 \rightarrow 0$
- ◆  $ENB = 0 \text{ AND OFF-State Diagnostic Pulse Request}$
- ◆ Blanking and/or Filter timer ran till end
  - √ “Diagnostic Complete”

#### Transition Trigger Events:

- Diagnostic status can transition from one state to another by several trigger events:
  - ◆ ON and/or OFF state diagnostic completed
  - ◆ SPI Read of the status register(s)
  - ◆ Recovery from VLOAD undervoltage detected
  - ◆ Reset via POR or RSTB

**Table 19. DIAGNOSTIC STATE TRANSITIONS**

Entering State	Description	Entering Criteria	Exiting Criteria	Exiting State
001	[SCB] – Short Circuit to Battery	SCB Detected	READ	111

### Diagnostic Status and Protection Interactions

The following figures are graphical representations of some interactions between diagnostics and protections.

The following assumptions apply:

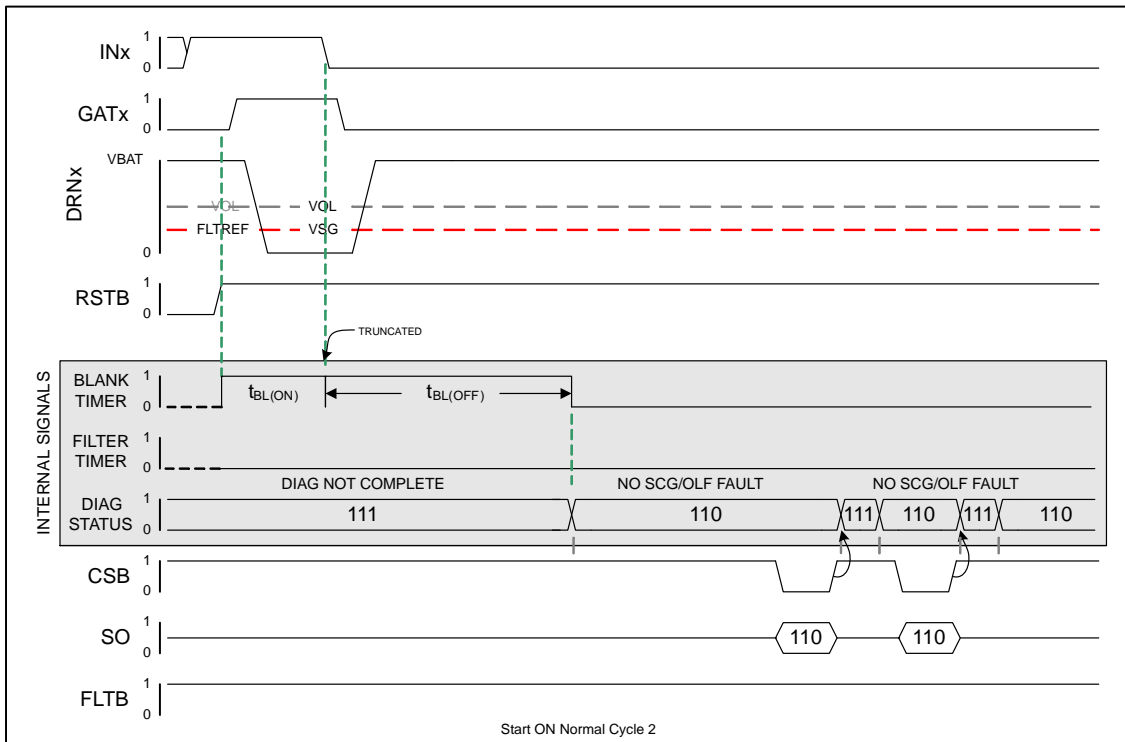

- ◆ Actual NCV7518 response is **one frame behind**
- SPI Frames are always valid
  - ◆ Integer multiples of 16 SCLK cycles
  - ◆ No parity errors

- ENB = 0
- SPI Response is shown in-frame
